### Background

Recently, Lin & Hu (2018, 2019) unraveled the biology of *Trictenotoma formosana* Kriesche, 1919. For the first time since Gahan (1908) there is fresh immature stages material available for Trictenotomidae.

The number of sternata in beetle larvae is used widely in morphology-based phylogenetic analysis. An uncommon difference between first-instar and last-instar trictenotomid larvae was uncovered during our study.

The presence of a series of longitudinal ridges on the tergites and sternites is one of the most important features of trictenotomid larvae compared with other Tenebrionoidea. The ridges are not present in first-instar larvae, but long setae are present instead.

### Results

Figure 1. Habitus of last-instar larva of *Trictenotoma formosana* Kriesche, 1919. A — dorsal view, B — ventral view. Scale bar: 20 mm.

Figure 2. Habitus of first-instar larva of *Trictenotoma formosana* Kriesche, 1919. A — dorsal view, B — ventral view. Scale bar: 500 um.

### Conclusions

1. Based on our observations, in the first instar larvae of *Trictenotoma formosana* 2-5 sternata are present on each side of the head, but absent in last-instar larvae. The ontogenetic importance of this phenomenon remains unknown.

2. A series of longitudinal ridges on the tergites and sternites is one of the most important features of trictenotomid larvae, which are present on last-instar larvae instead of long setae in first-instar larvae. We hypothesize that the longitudinal ridges of last-instar and setae of the first-instar might be homologous.
